AI-Powered Resume Ranker

Abstract

In today's competitive job market, organizations receive a large number of resumes for a single job opening, making manual screening time-consuming and inefficient. The AI-Powered Resume Ranker is designed to automate the process of resume evaluation using Natural Language Processing (NLP) techniques. This system extracts textual content from resumes, preprocesses the data, and compares it with a given job description to determine relevance. By using TF-IDF vectorization and cosine similarity, the system assigns a score to each resume and ranks candidates accordingly. The solution improves hiring efficiency, reduces human bias, and helps recruiters identify the most suitable candidates quickly.

Introduction

Recruitment is a critical process in any organization, but traditional methods of resume screening are often slow and prone to errors. Recruiters must manually read through hundreds of resumes, which can lead to inconsistencies and missed opportunities. With the advancement of Artificial Intelligence and NLP, it is possible to automate and enhance this process.

The AI-Powered Resume Ranker leverages machine learning techniques to analyze resumes and match them with job requirements. It processes resumes in PDF format, extracts relevant text, and evaluates how closely each resume aligns with the job description. This system not only saves time but also ensures a more objective and data-driven selection process.

Objectives

The main objectives of this project are:

To automate resume screening using NLP techniques

To extract meaningful information from PDF resumes

To compare resumes with job descriptions effectively

To rank candidates based on relevance scores

To provide a user-friendly web interface for recruiters

System Methodology

1. Text Extraction

The system uses PyPDF2 to extract text from uploaded PDF resumes. This step converts unstructured resume data into machine-readable text.

2. Text Preprocessing

Using SpaCy, the extracted text is cleaned and processed by:

Converting text to lowercase

Removing stop words

Lemmatizing words

Filtering irrelevant tokens

This ensures that only meaningful information is retained for analysis.

3. Feature Extraction

TF-IDF (Term Frequency-Inverse Document Frequency) is used to convert text into numerical vectors. This method highlights important keywords and reduces the impact of common words.

4. Similarity Calculation

Cosine similarity is applied to measure the similarity between the job description and each resume. A higher similarity score indicates a better match.

5. Ranking Mechanism
The system ranks resumes based on their similarity scores in descending order. The top-ranked candidates are the most suitable for the job.

System Architecture
The system follows a pipeline structure:
User uploads resumes and job description
Text is extracted from resumes
Data is pre-processed using NLP
Features are generated using TF-IDF
Similarity scores are computed
Candidates are ranked and displayed

Tools and Technologies
Python – Core programming language
Flask – Web framework for application development
SpaCy – NLP library for text processing
Scikit-learn – Machine learning tools (TF-IDF, cosine similarity)
PyPDF2 – PDF text extraction
Pandas – Data handling and report generation
HTML/CSS/JavaScript – Frontend development

Results and Discussion
The system successfully ranks resumes based on their relevance to a job description. It reduces manual effort and speeds up the recruitment process. The results are displayed in a structured format, showing each resume along with its score. Additionally, a downloadable report allows HR professionals to store and review candidate rankings.
The accuracy of the system depends on the quality of preprocessing and the relevance of keywords in the job description. While the system performs well for keyword-based matching, further improvements can enhance semantic understanding.

Advantages
Saves time and effort in resume screening
Reduces human bias in candidate selection
Provides consistent and objective evaluation
Easy to use with a web-based interface
Generates downloadable reports for HR

Limitations
Relies heavily on keyword matching
May not fully understand context or experience depth
Performance depends on resume formatting
Limited handling of complex semantic relationships

Conclusion
The AI-Powered Resume Ranker is an effective solution for automating the resume screening process. By integrating NLP and machine learning techniques, it provides a fast, accurate, and scalable method for evaluating candidates. The system

enhances recruitment efficiency and supports better decision-making for HR professionals.

Future Enhancements

Integration of deep learning models (BERT) for better semantic understanding
Skill extraction and categorization
Experience-based scoring
Real-time dashboard with analytics
User authentication and HR management system
Deployment on cloud platforms
